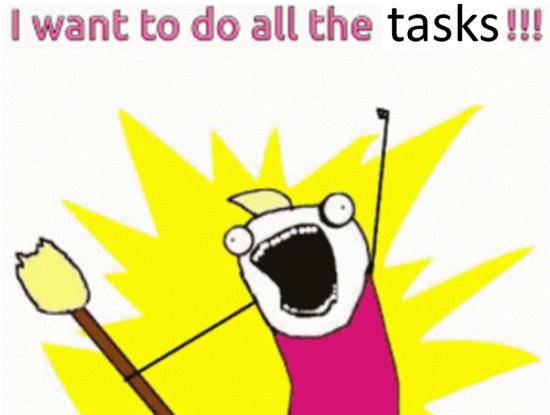
Multi-Task Learning Basics

CS 330



Logistics

Homework 0 due **Monday 10/3** at **11:59 pm PT**.

PyTorch review session **tomorrow at 4:30 pm PT.**

Office hours start today

Plan for Today

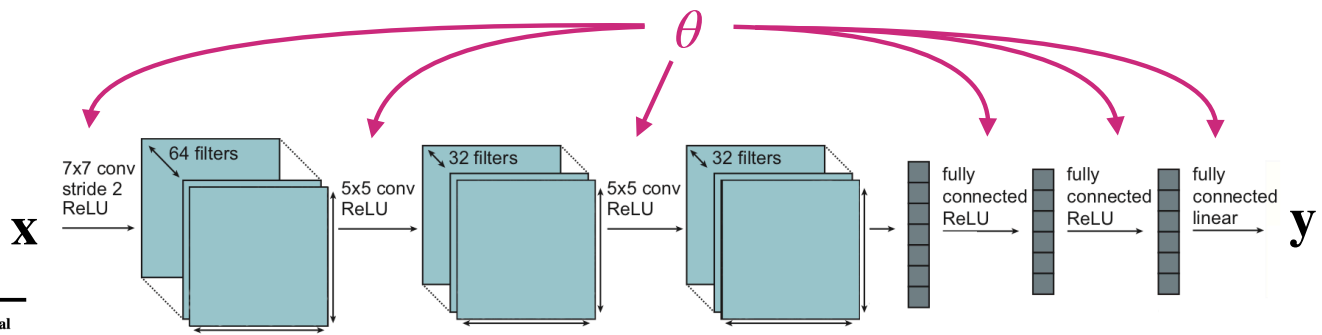
Multi-Task Learning
- Problem statement
- Models, objectives, optimization
- Challenges
- Case study of real-world multi-task learning

Goals for by the end of lecture:
- Understand the key design decisions when building multi-task learning systems

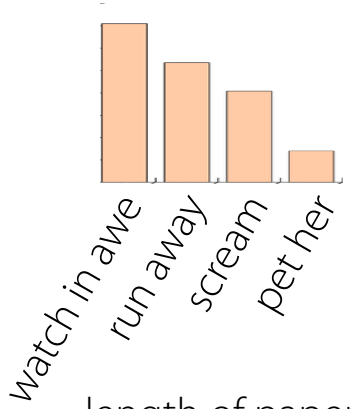
Multi-Task Learning

Some notation

ImageNet Classification with Deep Convolutional Neural Networks



$$f_\theta(\mathbf{y} \mid \mathbf{x})$$



length of paper

Single-task learning: [supervised]

$$\mathcal{D} = \{(\mathbf{x}, \mathbf{y})_k\}$$

$$\min_\theta \mathcal{L}(\theta, \mathcal{D})$$

Typical loss: negative log likelihood

$$\mathcal{L}(\theta, \mathcal{D}) = -\mathbb{E}_{(x,y)\sim\mathcal{D}}[\log f_\theta(\mathbf{y} \mid \mathbf{x})]$$

What is a task? (more formally this time)

A task: $\mathcal{T}_i \triangleq \{p_i(\mathbf{x}), p_i(\mathbf{y} \mid \mathbf{x}), \mathcal{L}_i\}$

data generating distributions

Corresponding datasets: $\mathcal{D}_i^{tr}$ $\mathcal{D}_i^{test}$

will use $\mathcal{D}_i$ as shorthand for $\mathcal{D}_i^{tr}$:

Examples of Tasks

A task: $\mathcal{T}_i \triangleq \{p_i(\mathbf{x}), p_i(\mathbf{y}\,|\,\mathbf{x}), \mathcal{L}_i\}$

data generating distributions

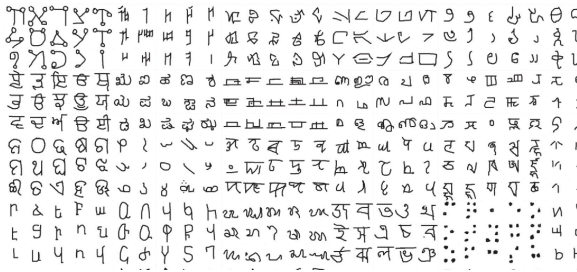
Corresponding datasets: $\mathcal{D}_i^{tr}$ $\mathcal{D}_i^{test}$

will use $\mathcal{D}_i$ as shorthand for $\mathcal{D}_i^{tr}$:

Multi-task classification: $\mathcal{L}_i$ same across all tasks

Omniglot Dataset

e.g. per-language handwriting recognition

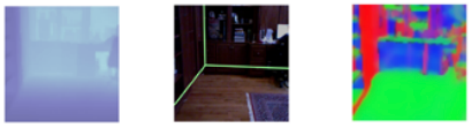


e.g. personalized spam filter

Multi-label learning: $\mathcal{L}_i$, $p_i(\mathbf{x})$ same across all tasks

e.g. face attribute recognition

e.g. scene understanding

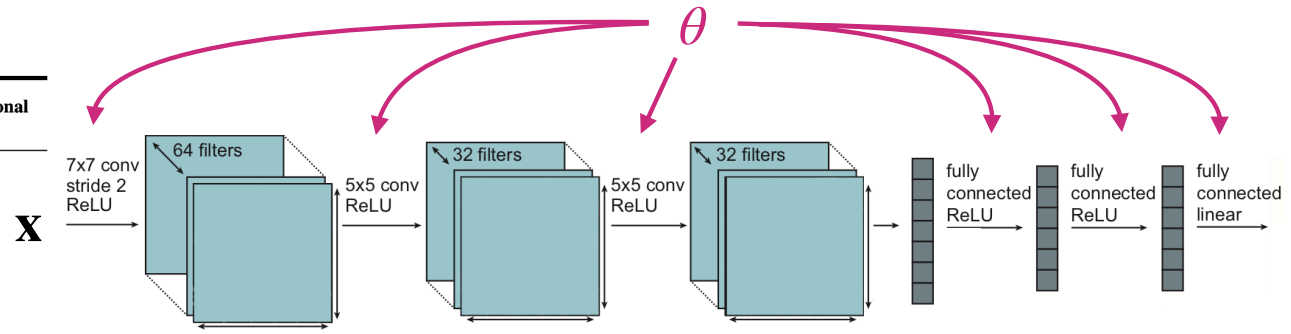


$$L_{\text{tot}} = w_{\text{depth}} L_{\text{depth}} + w_{\text{kpt}} L_{\text{kpt}} + w_{\text{normals}} L_{\text{normals}}$$

When might $\mathcal{L}_i$ vary across tasks?

- mixed discrete, continuous labels across tasks
- multiple metrics that you care about

ImageNet Classification with Deep Convolutional Neural Networks



Examples of task descriptor
- length of paper
- summary of paper
- paper review

summary

paper review (eg)

$\mathbf{z}_i$

task descriptor

Tell the neural network what the task is.

$f_\theta(\mathbf{y} \mid \mathbf{x})$ $f_\theta(\mathbf{y} \mid \mathbf{x}, \mathbf{z}_i)$

this is added

e.g. one-hot encoding of the task index

or, whatever meta-data you have

Could also be text-prompt

- personalization: user features/attributes
- language description of the task
- formal specifications of the task

Vanilla MTL Objective

$$\min_\theta \sum_{i=1}^{T} \mathscr{L}_i(\theta, \mathscr{D}_i)$$

T → tasks

Decisions on the model, the objective, and the optimization.

How should we condition on $\mathbf{z}_i$?

What objective should we use?

How to optimize our objective?

Model	How should the model be conditioned on $\mathbf{z}_i$? What parameters of the model should be shared?
Objective	How should the objective be formed?
Optimization	How should the objective be optimized?

Conditioning on the task

Let's assume $\mathbf{z}_i$ is the one-hot task index.

Question: How should you condition on the task in order to share as little as possible?

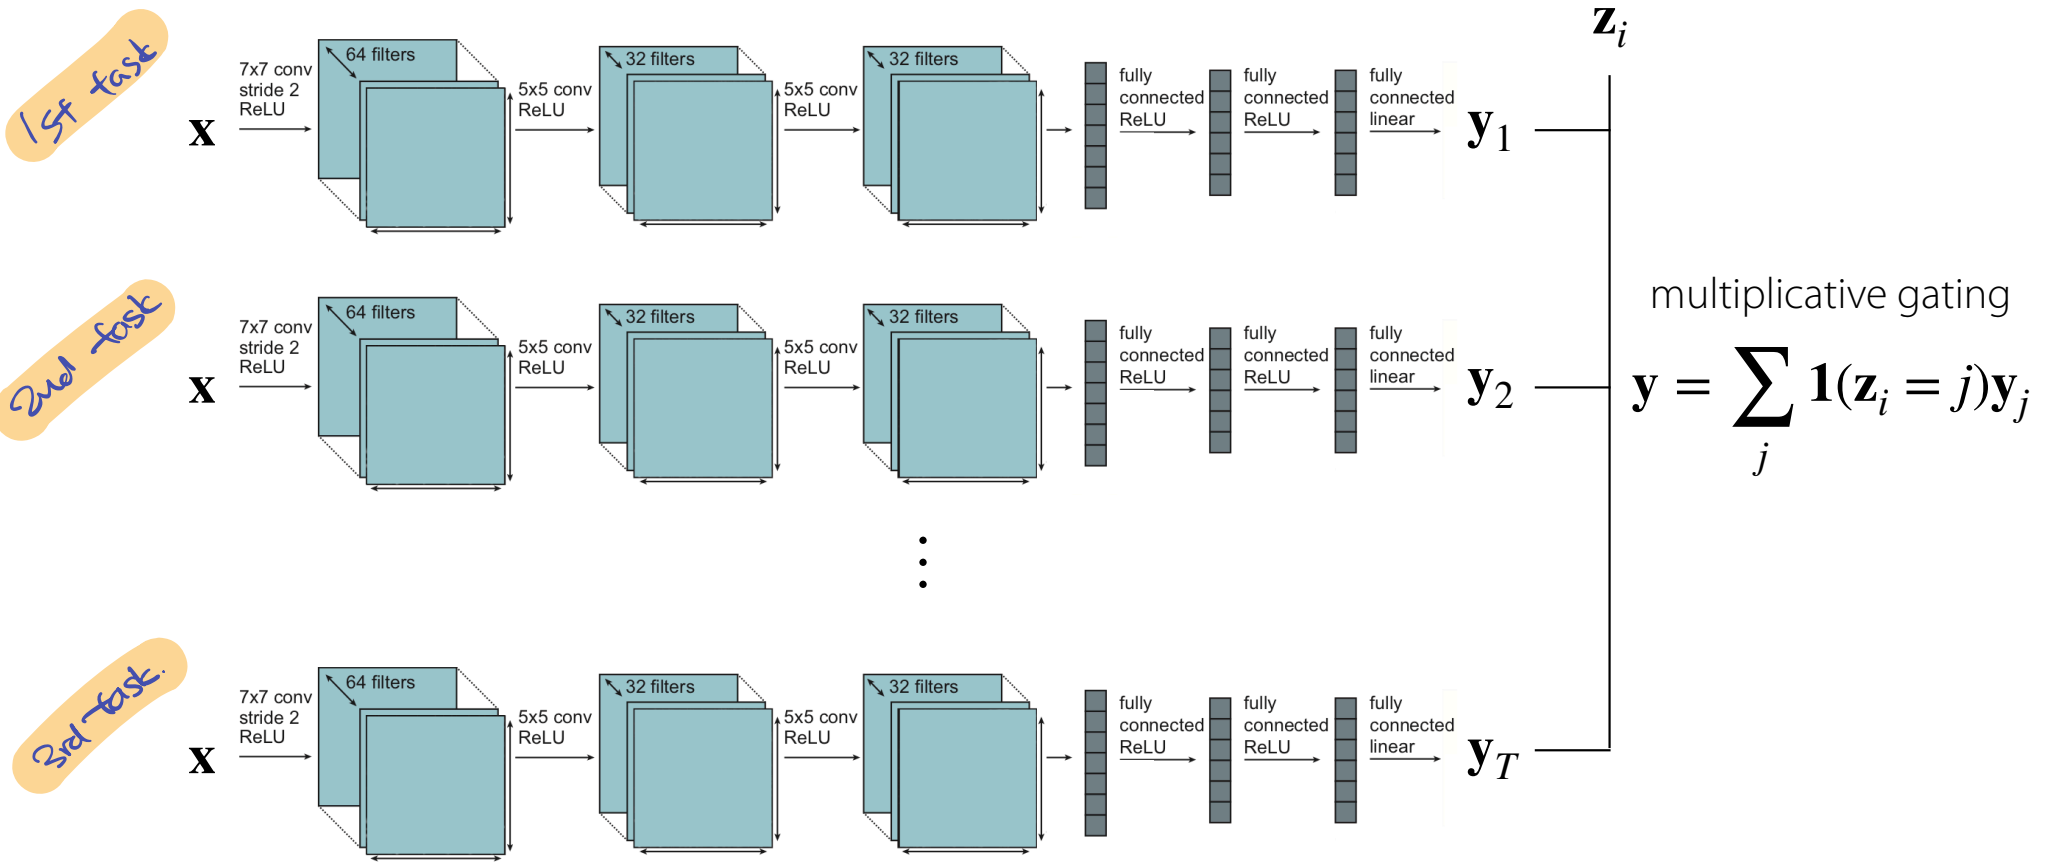
↳ i.e. we want to have as few params for different tasks to be shared.

⇒ Just 3 separate models? For each one-hot encoding (a switch statement)

Q: How are we going to condition on z_i?

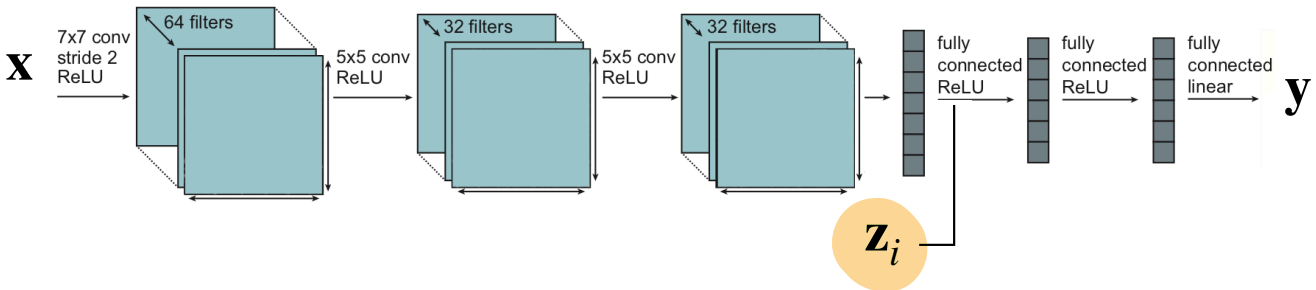
Conditioning on the task

Not a great way to go about MTL.



—> independent training within a single network!
with no shared parameters

The other extreme



Concatenate $\mathbf{z}_i$ with input and/or activations

all parameters are shared
(except the parameters directly following $\mathbf{z}_i$, if $\mathbf{z}_i$ is one-hot)

An Alternative View on the Multi-Task Architecture

Split θ into shared parameters θ^{sh} and task-specific parameters θ^i

Then, our objective is: $\min_{\theta^{sh},\theta^1,\ldots,\theta^T} \sum_{i=1}^{T} \mathcal{L}_i(\{\theta^{sh}, \theta^i\}, \mathcal{D}_i)$

↳ Writing it this way is useful ∵ shows us that the task-specific params for task i (θ^i) are only optimized w.r.t. $\mathcal{L}_i$.

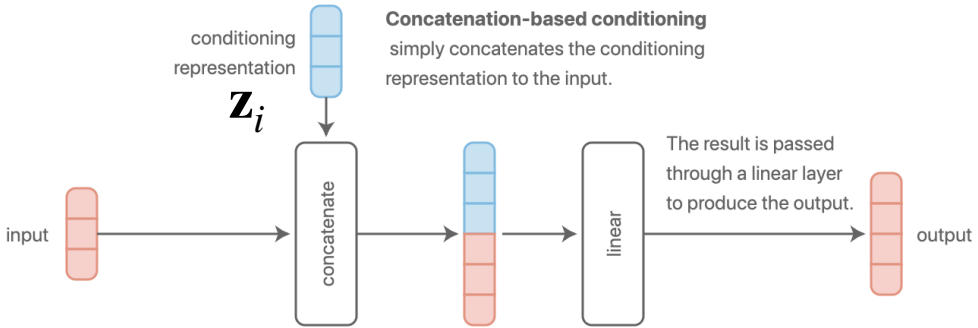
Choosing how to condition on $\mathbf{z}_i$

equivalent to

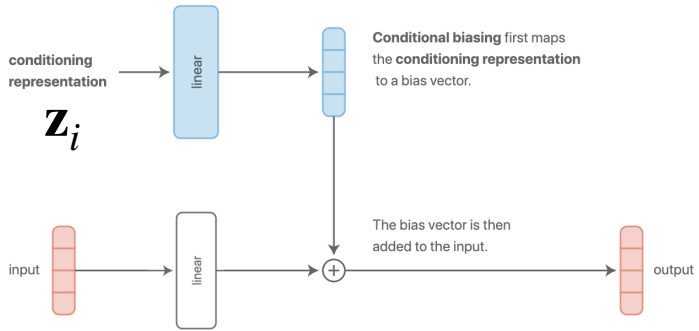
Choosing how & where to share parameters

Conditioning: Some Common Choices

1. **Concatenation-based** conditioning



2. **Additive** conditioning



These are actually equivalent!

Question: why are they the same thing? (raise your hand)

Concat followed by a fully-connected layer:

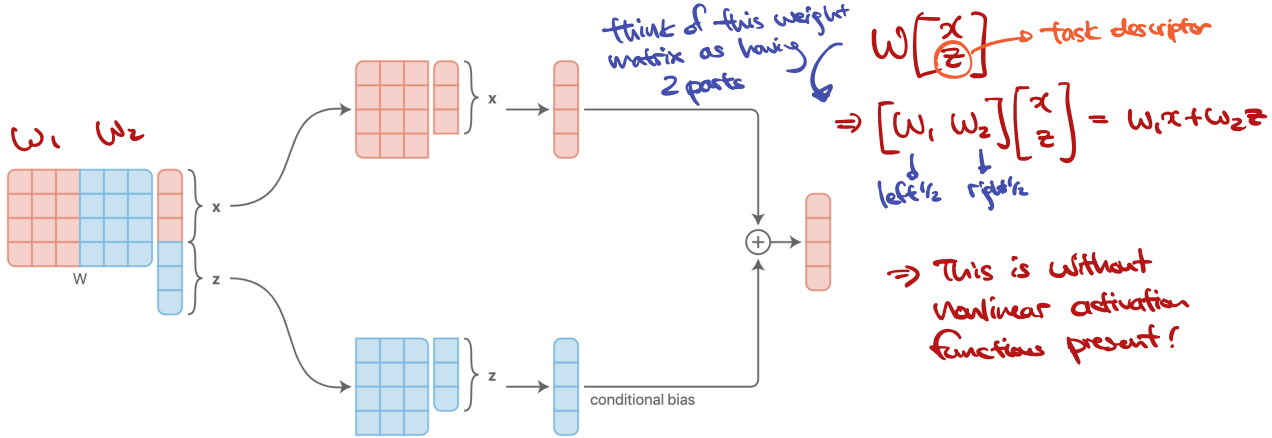


Diagram sources: distill.pub/2018/feature-wise-transformations/

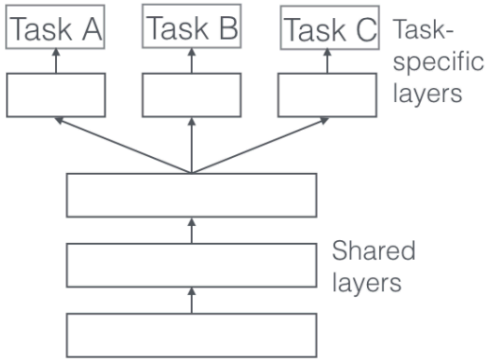
Conditioning: Some Common Choices

3. Multi-head architecture

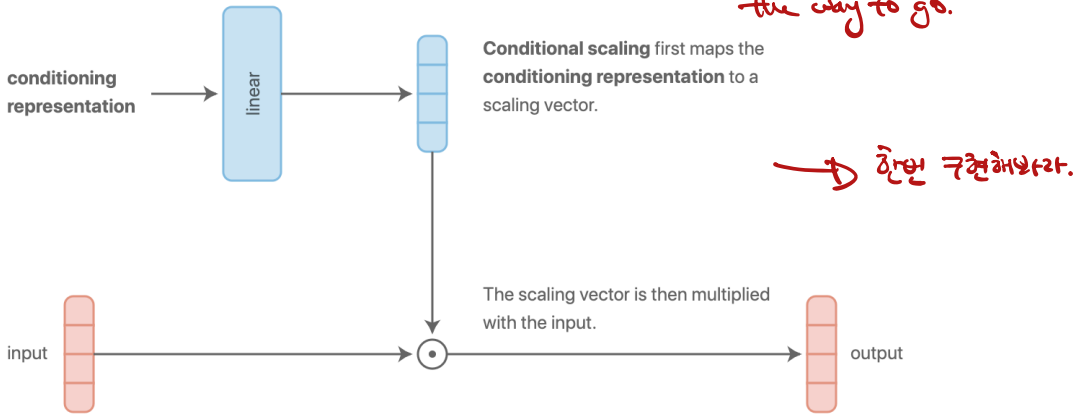


Ruder '17

generalization →

4. Multiplicative conditioning

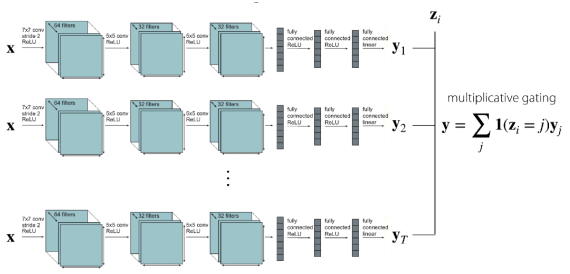
Generally the way to go.



한번 구현해보라.

Why might multiplicative conditioning be a good idea?

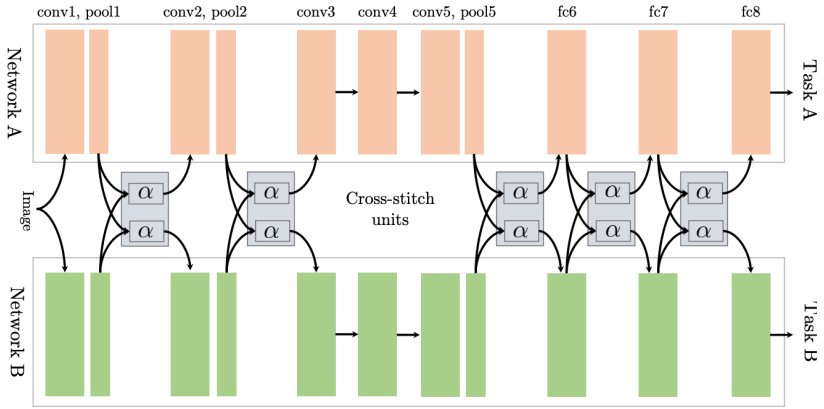
- more expressive per layer
- recall: multiplicative gating



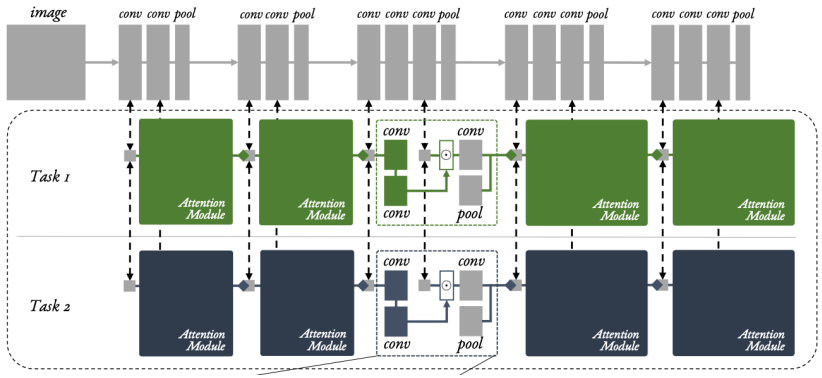
Multiplicative conditioning **generalizes** independent networks and independent heads.

Diagram sources: distill.pub/2018/feature-wise-transformations/

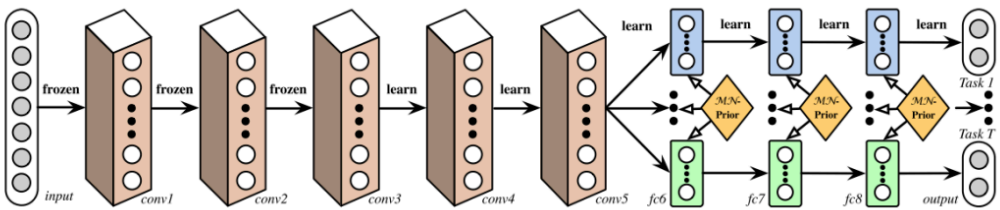
Conditioning: More Complex Choices



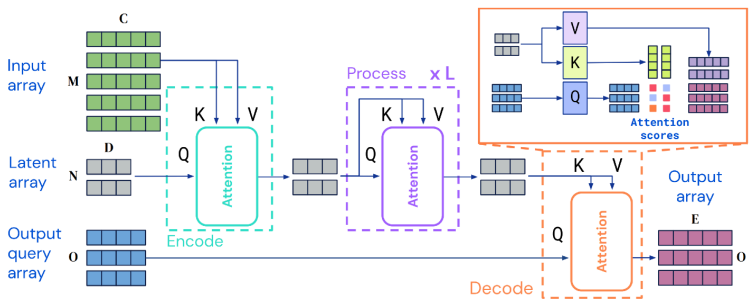
Cross-Stitch Networks. Misra, Shrivastava, Gupta, Hebert '16



Multi-Task Attention Network. Liu, Johns, Davison '18



Deep Relation Networks. Long, Wang '15

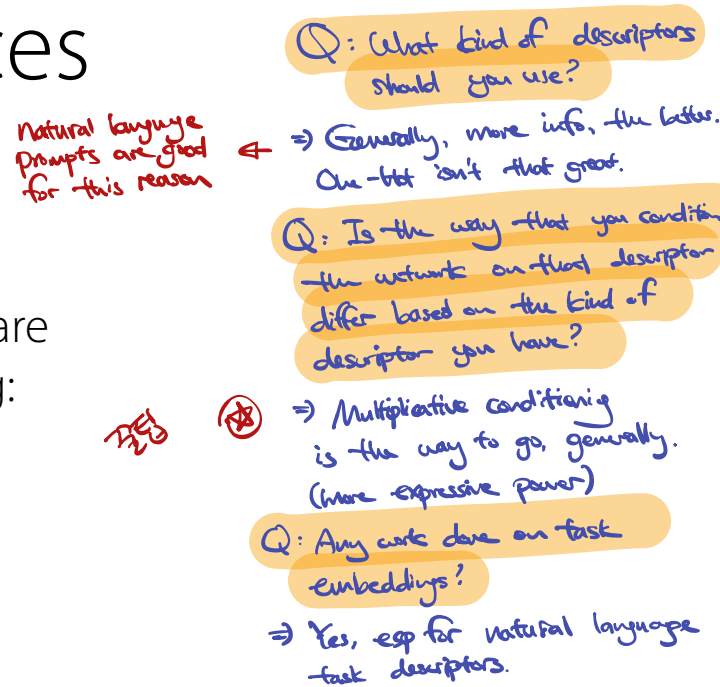


Perceiver IO. Jaegle et al. '21

Conditioning Choices

Unfortunately, these design decisions are like neural network architecture tuning:

- **problem dependent**
- largely guided by **intuition** or **knowledge** of the problem
- currently more of an **art** than a science



Model	How should the model be conditioned on $\mathbf{z}_i$? What parameters of the model should be shared?
Objective	How should the objective be formed?
Optimization	How should the objective be optimized?

Vanilla MTL objective:

$$\min_{\theta} \sum_{i=1}^{T} \mathscr{L}_i(\theta, \mathscr{D}_i)$$

Often want to weight tasks differently:

$$\min_{\theta} \sum_{i=1}^{T} w_i \mathscr{L}_i(\theta, \mathscr{D}_i)$$

How to choose w_i?

- manually based on importance or priority
- *dynamically* adjust throughout training
  - if the model gets stuck doing a task, (temporarily) increase the weights for that task.

a. various heuristics
- some tasks might matter more than others.

encourage gradients to have similar magnitudes
(Chen et al. GradNorm. ICML 2018)
- pretty large body of work

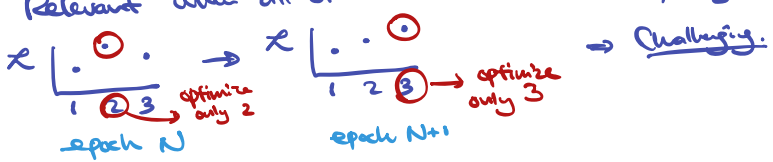
b. optimize for the worst-case task loss
- Try vanilla, & if our task isn't performing well, increase weight for that one.

DRO: Distributionally Robust Optimization

$$\min_{\theta} \max_{i} \mathscr{L}_i(\theta, \mathscr{D}_i)$$

(e.g. for task robustness, or for fairness)

minimax optimization.
- ⇒ Highest loss → optimize param for that task
- ⇒ Relevant when all of the tasks matter equally
- ⇒ Challenging.



Model	How should the model be conditioned on $\mathbf{z}_i$? What parameters of the model should be shared?
Objective	How should the objective be formed?
Optimization	How should the objective be optimized?

Optimizing the objective

Vanilla MTL Objective: $\min_{\theta} \sum_{i=1}^{T} \mathscr{L}_i(\theta, \mathscr{D}_i)$

Basic Version:

If you care about one task more than others, sample accordingly.

Uniform sampling, regardless of the relative quantity of the data.

Definition of a Task.

a) $\mathscr{T}_i \triangleq \{P_i(x), P_i(y|x), \mathscr{L}_i\}$

1. Sample mini-batch of tasks $\mathscr{B} \sim \{\mathscr{T}_i\}$
2. Sample mini-batch datapoints for each task $\mathscr{D}_i^b \sim \mathscr{D}_i$
3. Compute loss on the mini-batch: $\hat{\mathscr{L}}(\theta, \mathscr{B}) = \sum_{\mathscr{T}_k \in \mathscr{B}} \mathscr{L}_k(\theta, \mathscr{D}_k^b)$
4. Backpropagate loss to compute gradient $\nabla_\theta \hat{\mathscr{L}}$
5. Apply gradient with your favorite neural net optimizer (e.g. Adam)

Note: This ensures that tasks are sampled uniformly, regardless of data quantities.

Tip: For regression problems, make sure your task labels are on the same scale!

Normalize your labels!

Challenges

Challenge #1: Negative transfer

Multi-task performing worse than individually-trained

Negative transfer: Sometimes independent networks work the best.

example

Multi-Task CIFAR-100

recent approaches

	% accuracy	
task specific, 1-fc (Rosenbaum et al., 2018)	42	} multi-head architectures
task specific, all-fc (Rosenbaum et al., 2018)	49	} multi-head architectures
cross stitch, all-fc (Misra et al., 2016b)	53	} cross-stitch architecture
independent	67.7	} independent training

(Yu et al. Gradient Surgery for Multi-Task Learning. 2020)

Why?

- **optimization challenges**
  - caused by cross-task interference
  - tasks may learn at different rates
- **limited representational capacity**
  - multi-task networks often need to be *much larger* than their single-task counterparts

If you have negative transfer, **share less** across tasks.

→ To see negative transfer, train independently ~ compare!

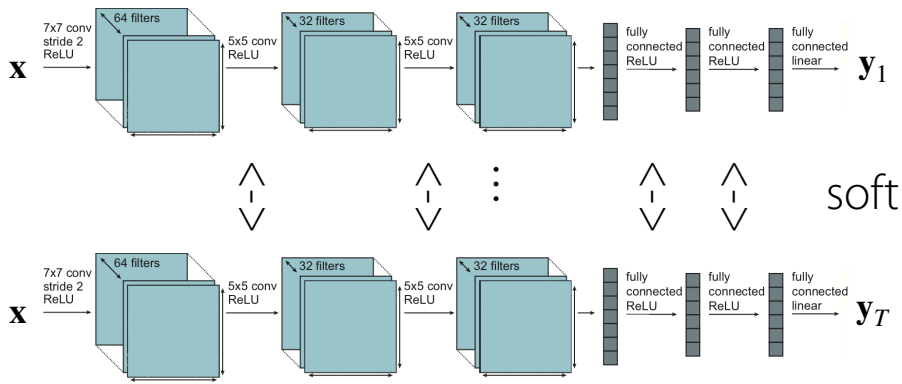
→ or pre-train on one task, and fine-tune on another.

It's not just a binary decision!

$$\min_{\theta^{sh},\theta^1,\ldots,\theta^T} \sum_{i=1}^{T} \mathscr{L}_i(\{\theta^{sh},\theta^i\},\mathscr{D}_i) + \lambda \underbrace{\sum_{i'=1}^{T} \|\theta^i - \theta^{i'}\|}$$

"soft parameter sharing"

→ encourage params to be similar.
⇒ middle ground between sharing ~ not sharing
⇒ Adjust using λ.



softly constrained weights

+ allows for more fluid degrees of parameter sharing

- yet another set of design decisions / hyperparameters

- more memory intensive

Challenge #2: Overfitting

↳ Opposite of Negative Transfer.

You may not be sharing enough!

Multi-task learning <-> a form of regularization

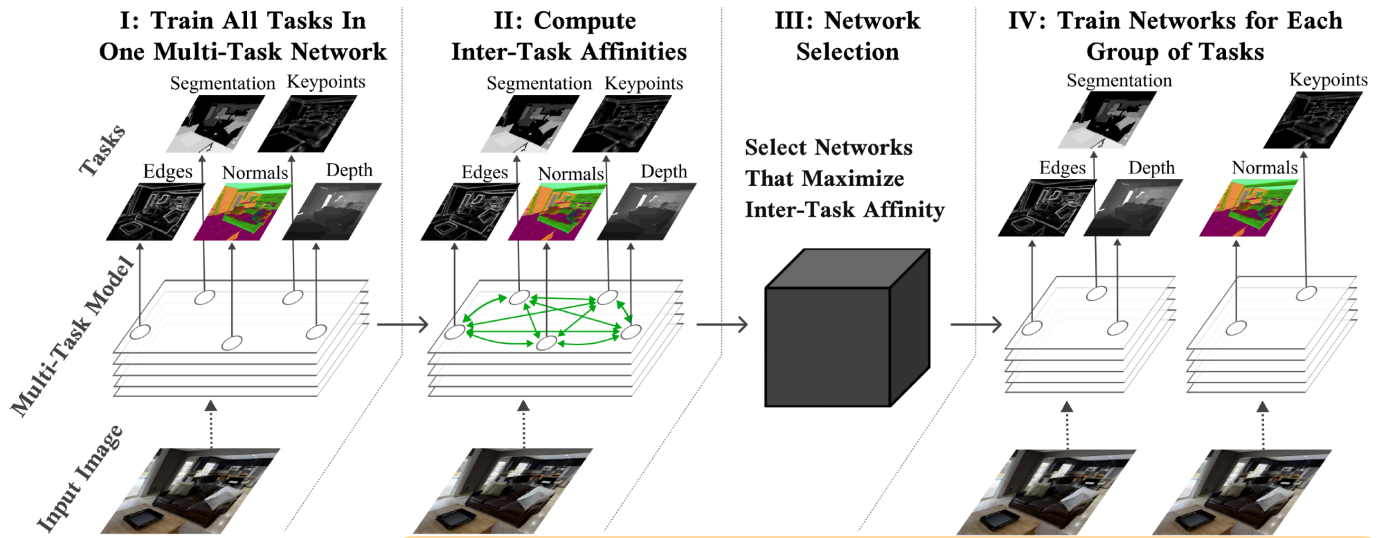
Solution: Share more.

Challenge #3: What if you have a lot of tasks?

Should you train all of them together? Which ones will be complementary?

The bad news: No closed-form solution for measuring task similarity.

The good news: There are ways to approximate it from one training run. → Trial ~ Error



Fifty, Amid, Zhao, Yu, Anil, Finn. *Efficiently Identifying Task Groupings for Multi-Task Learning*. NeurIPS 2021

Multi-Task Learning Recap

A task: $\mathcal{T}_i \triangleq \{p_i(\mathbf{x}), p_i(\mathbf{y}\,|\,\mathbf{x}), \mathcal{L}_i\}$

Corresponding datasets: $\mathcal{D}_i^{tr}$ $\mathcal{D}_i^{test}$

Model Architecture

- multiplicative vs. additive conditioning on $\mathbf{z}_i$
- share more vs. less depending on observed transfer

Objective & Optimization

$$\min_{\theta} \sum_{i=1}^{T} w_i \mathcal{L}_i(\theta, \mathcal{D}_i^{tr})$$

- choosing task weights
- stratified mini-batches

Recommending What Video to Watch Next: A Multitask Ranking System

Zhe Zhao, Lichan Hong, Li Wei, Jilin Chen, Aniruddh Nath, Shawn Andrews, Aditee Kumthekar, Maheswaran Sathiamoorthy, Xinyang Yi, Ed Chi
Google, Inc.
{zhezhao,lichan,liwei,jilinc,aniruddhnath,shawnandrews,aditeek,nlogn,xinyang,edchi}@google.com

Goal: Make recommendations for YouTube

What video should go here?

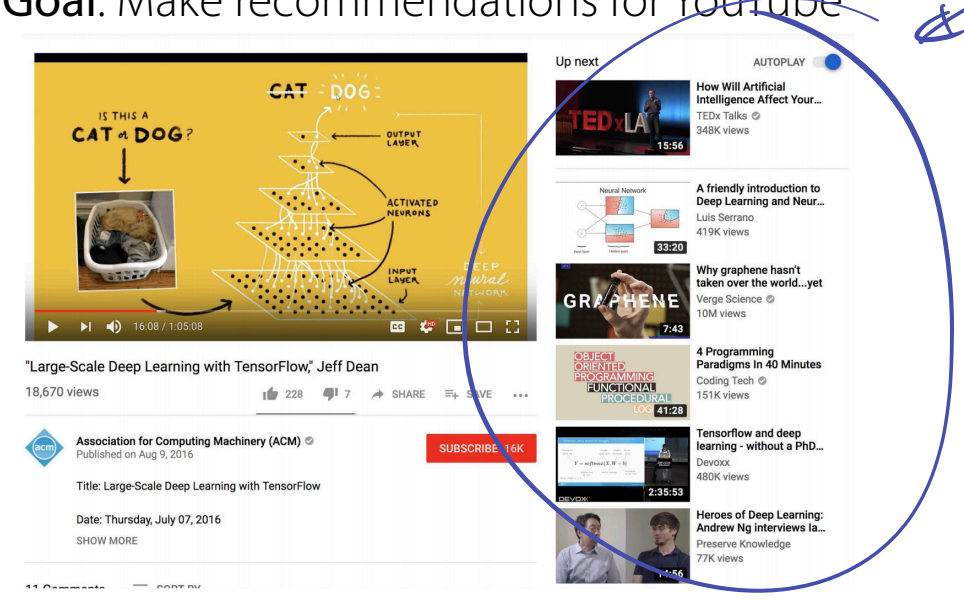

Figure 4: Recommending what to watch next on YouTube.

Framework Set-Up

Input: what the user is currently watching (query video) + user features

1. Generate a few hundred of candidate videos
2. Rank candidates
3. Serve top ranking videos to the user

Candidate videos: pool videos from multiple candidate generation algorithms

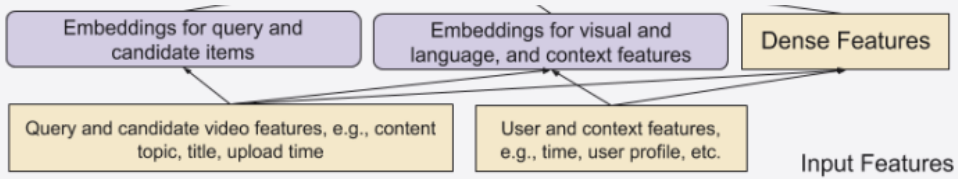
- matching topics of query video
- videos most frequently watched with query video
- And others

Ranking: central topic of this paper

The Ranking Problem

Issues
- missing data
- time spent → long v short videos
- lot less survey data
- engagement high but low likes
- feedback loops.
- exploration vs. exploitation

Input: query video, candidate video, user & context features



Model output: engagement and satisfaction with candidate video

Engagement:
- binary classification tasks like **clicks**
- regression tasks related to **time spent**

Satisfaction:
- binary classification tasks like **clicking "like"**
- regression tasks such as **rating**

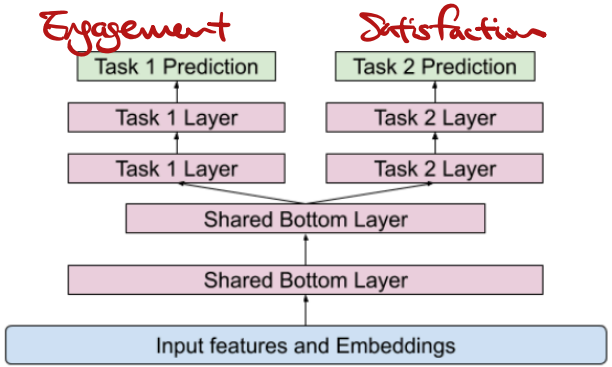
Weighted combination of **engagement** & **satisfaction** predictions -> **ranking score**
score weights manually tuned

Question: Are these objectives reasonable? What are some of the issues that might come up?

The Architecture

Basic option: "Shared-Bottom Model"

(i.e. multi-head architecture)



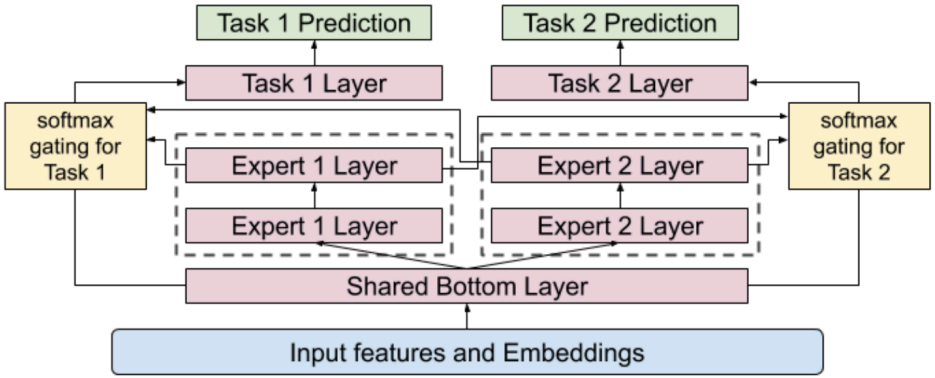
(a) Shared-Bottom Model with shared bottom hidden layers and separate towers for two tasks.

-> harms learning when correlation between tasks is low

The Architecture

Instead: use a form of soft-parameter sharing

"Multi-gate Mixture-of-Experts (MMoE)"



(b) Multi-gate Mixture-of-Expert Model with one shared bottom layer and separate hidden layers for two tasks.

Allow different parts of the network to "specialize"

expert neural networks $f_i(x)$

Decide which expert to use for input x, task k:

$$g^k(x) = \text{softmax}(W_{g^k} x)$$

Compute features from selected expert:

$$f^k(x) = \sum_{i=1}^{n} g^k_{(i)}(x) f_i(x)$$

Compute output:

$$y_k = h^k(f^k(x)),$$

Experiments

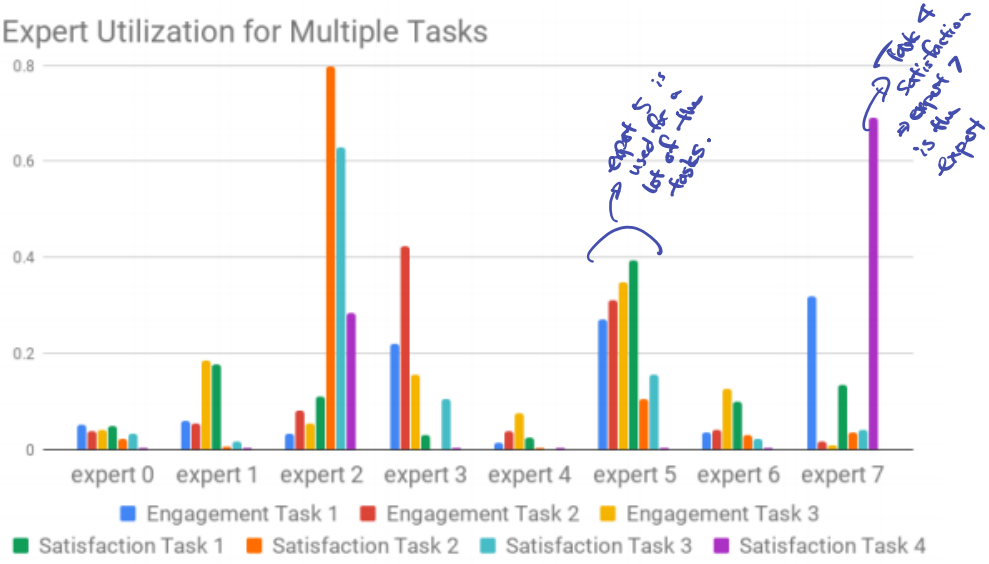
Set-Up

- Implementation in TensorFlow, TPUs
- Train in ***temporal order***, running training continuously to consume newly arriving data
- **Online A/B testing** in comparison to production system
  - live metrics based on time spent, survey responses, rate of dismissals
- Model **computational efficiency** matters

Results

Model Architecture	Number of Multiplications	Engagement Metric	Satisfaction Metric
Shared-Bottom	3.7M	/	/
Shared-Bottom	6.1M	+0.1%	+ 1.89%
MMoE (4 experts)	3.7M	+0.20%	+ 1.22%
MMoE (8 Experts)	6.1M	+0.45%	+ 3.07%

Table 1: YouTube live experiment results for MMoE.



Found 20% chance of gating polarization during distributed training -> use drop-out on experts

Lecture Recap

- Multi-task learning learns neural network conditioned on task descriptor $\mathbf{z}_i$
- Choice of task weighting w_i affects prioritization of tasks.
- Choice of how to condition on $\mathbf{z}_i$ affects how parameters are shared.
  - If you observe negative transfer, share less.
    If you observe overfitting, try sharing more.

Goals for by the end of lecture:

- Understand the key design decisions when building multi-task learning systems

Reminders
